ProjectName	**Implement Client Script & UI Policy (Incident)**
Maximum Marks	3 Marks

Mandatory Validation – onSubmit Client Script

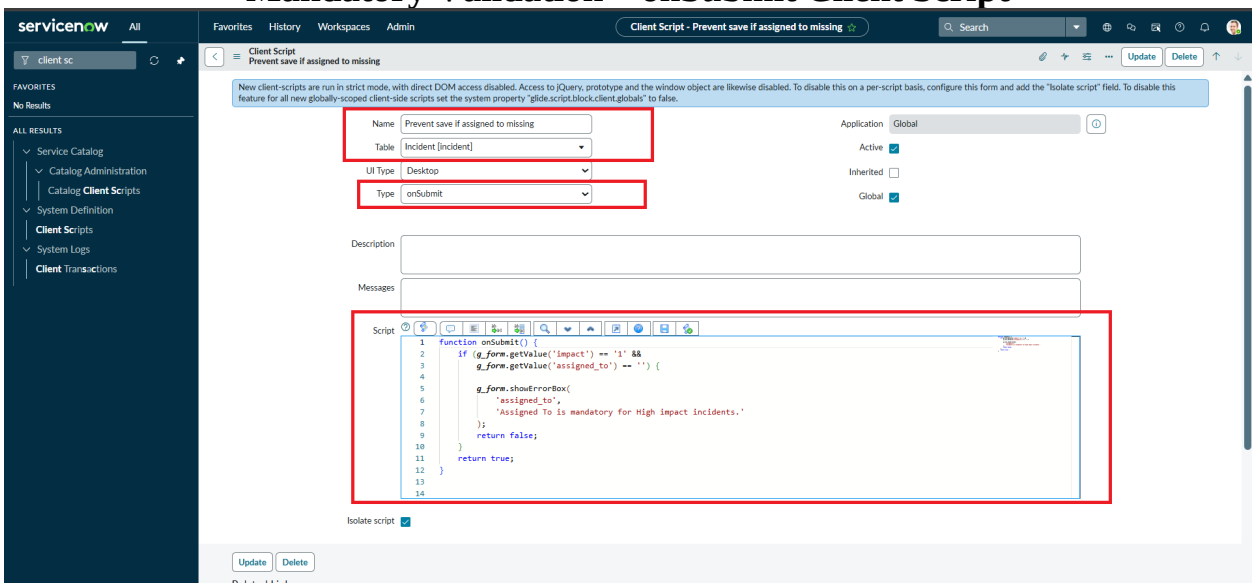

Figure: Mandatory Validation Client Script Configuration

The screenshot above shows the ServiceNow Client Script configuration used for mandatory validation on Incident records. The Client Script is named “Prevent save if assigned to missing,” is associated with the Incident table, and uses the onSubmit type. This means the validation is executed when the user attempts to save or submit an Incident record.

The script checks two conditions before allowing the Incident to be saved: the Impact field must have the value High, and the Assigned To field must not be empty. If Impact is High and Assigned To is missing, the script displays an error message stating that Assigned To is mandatory for High impact incidents and returns false, thereby preventing the record from being submitted.

This validation provides an additional layer of data integrity for high-impact incidents. The project instructions specify that testing should include attempting to save an Incident with High Impact while leaving Assigned To empty; the save should be blocked and a warning should be displayed. When a valid Assigned To value is provided, the validation condition is satisfied and the Incident can be saved normally.
